## 1 Description of the syntax of the maximum likelihood module

```
[beta,stderr,vc,logl]=Max_lik(lik_fct,b0,vc_type,A,b,Aeq,beq,lb,ub,nonlcon,options,varargin);
```

## 2 Description

This module performs the estimation of a parameter vector via maximum likelihood. This estimation is largely built around the Matlab procedure that computes constrained minimization named `fmincon`. Many of the parameters need to be provided to that optimizer.

## 3 Input parameters

**lik\_fct** a function handle

**b0** the initial values

**vc\_type** instructions which variance-covariance matrix to implement. Currently available procedures are Hessian and White's Sandwiched method.

the next set of parameters is feed to the optimizer. We use the optimizer in its most general way.

### 3.1 `fmincon`

The optimizer gets called with:

`fmincon(fun,x0,A,b,Aeq,beq,lb,ub,nonlcon,options,P1,P2,...)`

`fmincon` finds the constrained minimum of a scalar function of several variables starting at an initial estimate. This is generally referred to as constrained nonlinear optimization or nonlinear programming.

`fmincon` starts at **x0** and finds a minimum **x** to the function described in **fun** subject to the linear inequalities  $\mathbf{A}^*\mathbf{x} \leq \mathbf{b}$ . **x0** can be a scalar, vector, or matrix. It is possible to minimize **fun** subject to the linear equalities  $\mathbf{Aeq}^*\mathbf{x} = \mathbf{beq}$  as well as  $\mathbf{A}^*\mathbf{x} \leq \mathbf{b}$ . Set  $\mathbf{A}=[]$  and  $\mathbf{b}=[]$  if no inequalities exist. Set  $\mathbf{Aeq}=[]$  and  $\mathbf{beq}=[]$  if no equalities exist.

**lb** and **ub** defines a set of lower and upper bounds on the variables, **x**, so that the solution is always in the range  $\mathbf{lb} \leq \mathbf{x} \leq \mathbf{ub}$ . It is always possible to define **lb** and **ub** very large so that the constrained optimization can also be used for unconstrained optimization.

`nonlcon` subjects the minimization to the nonlinear inequalities **c(x)** or equalities **ceq(x)** defined in **nonlcon**. `fmincon` optimizes such that  $\mathbf{c}(\mathbf{x}) \leq 0$  and  $\mathbf{ceq}(\mathbf{x}) = 0$ . **options** minimizes with the optimization parameters specified in the structure 'options'. **P1,P2,...** passes the problem-dependent parameters P1, P2, etc., directly to the functions `fun` and `nonlcon`.

`[x,fval,exitflag,output,lambda,grad,hessian] = fmincon(...)` returns

**x** the minimum

**fval** the value of **f** evaluated at the minimum

**exitflag** a value that describes the exit condition of `fmincon`.

**output** a structure output with information about the optimization.

**lambda** is a structure **lambda** whose fields contain the Lagrange multipliers at the solution **x**.

**grad** returns the value of the gradient of `fun` at the solution **x**.

**hessian** returns the value of the Hessian of `fun` at the solution **x**.

## 3.2 fun

the function to be optimized should have as a first argument the vector of parameters over which the optimization should be done.

then the function may import a list of parameters.

It is possible to include in this list of parameters the vector of data. Typically this would be a vector containing  $T$  observations.

`fun` should export the vector of log-likelihoods.

## 4 Output parameters

**beta** vector of parameters that maximize the `log_likelihood`

**stderr** vector of associated standard errors. These standard errors get computed either via numerical hessians or via the sandwich method.

**vc** the variance covariance matrix. Again the same method as for `stderr` is used

**logl** the log-likelihood of the problem.
